ELISpot

Mouse IL-2

Catalog Number EL402

For the quantitative determination of the frequency of cells releasing mouse IL-2.

This package insert must be read in its entirety before using this product.
For research use only. Not for use in diagnostic procedures.

INTRODUCTION

Interleukin 2 (IL-2) is a pleiotropic cytokine produced transiently by T lymphocytes upon T cell antigen receptor (TCR) activation (1-4). It supports the clonal expansion and differentiation of antigen-activated CD4+ T helper cells as well as CD8+ cytolytic T cells. IL-2 also stimulates the proliferation and function of natural killer (NK) cells, B cells, monocytes/macrophages and oligodendrocytes (1-5).

Mouse IL-2 cDNA encodes a 169 amino acid (aa) precursor glycoprotein that contains a 20 aa putative signal peptide and a 149 aa mature O-glycosylated protein (1-8). Mature mouse IL-2 contains a poly-glutamine domain near its N-terminus not found in other IL-2 proteins (7,8). Mouse IL-2 is also highly polymorphic near its N-terminus. At least five different IL-2 alleles have been shown to exist in different mouse strains. Differences in activities have been reported for the different IL-2 alleles (9). Mouse IL-2 shares approximately 80%, 69%, 65%, and 57% aa sequence identity with rat, cotton rat, human and porcine IL-2, respectively (1, 10-13). Besides T cells, visceral smooth muscle cells (14), eosinophils (15,16,18) and B cells (17) have also been found to express IL-2.

The functional IL-2 receptor complex that transduces IL-2 signals is made up of three type I transmembrane proteins, the IL-2 Rα, IL-2 Rβ, and γς subunits (18,19). The IL-2 Rα subunit by itself can bind IL-2 with low affinity but does not transduce an IL-2 signal. In humans, the IL-2 Rβ subunit by itself can also bind IL-2 and forms a functional intermediate-affinity receptor in the presence of the γς subunit to transduce IL-2 signals (19,20). The mouse IL-2 Rβ subunit does not bind IL-2 and cannot form a functional intermediate-affinity IL-2 receptor in the presence of the γς subunit (21).

The Mouse IL-2 ELISpot assay is designed for the detection of mouse IL-2 secreting cells at the single cell level, and it can be used to quantitate the frequency of mouse IL-2 secreting cells. ELISpot assays are well suited for monitoring immune responses to various stimuli, treatments and therapies, and they have been used for the quantification of antigen-specific CD4+ and/or CD8+ T cell responses. Other methods for the assessment of antigen-specific T cell responses, such as the chromium release assays with quantitation by limiting dilution, are tedious and require previous in vitro expansion of T cells for several days. These assays typically are not suitable for measuring infrequent T cell responses that occur at less than 1 in 1000. ELISpot assays are highly reproducible and sensitive, and can be used to measure responses with frequencies well below 1 in 100,000. ELISpot assays do not require prior in vitro expansion of T cells, and they are suitable for high-throughput analysis using only small volumes of primary cells. As such, ELISpot assays are useful tools for research in areas as diverse as antigen recognition, vaccine development, cytokine secretion and the monitoring of various clinical trials.
**PRINCIPLE OF THE ASSAY**

The enzyme-linked immunospot (ELISpot) assay was originally developed for the detection of individual B cells secreting antigen-specific antibodies (22, 23). This method has since been adapted for the detection of individual cells secreting specific cytokines or other antigens (24, 25). ELISpot assays employ the quantitative sandwich enzyme-linked immunosorbent assay (ELISA) technique.

A monoclonal antibody specific for mouse IL-2 has been pre-coated onto a PVDF (polyvinylidene difluoride)-backed microplate. Appropriately stimulated cells are pipetted into the wells and the microplate is placed into a humidified 37 °C CO₂ incubator for a specified period of time. During this incubation period, the immobilized antibody in the immediate vicinity of the secreting cells binds secreted IL-2. After washing away any cells and unbound substances, a biotinylated polyclonal antibody specific for mouse IL-2 is added to the wells. Following a wash to remove any unbound biotinylated antibody, alkaline-phosphatase conjugated to streptavidin is added. Unbound enzyme is subsequently removed by washing and a substrate solution (BCIP/NBT) is added. A blue-black colored precipitate forms and appears as spots at the sites of cytokine localization, with each individual spot representing an individual IL-2 secreting cell. The spots can be counted with an ELISpot reader system or using a stereomicroscope.
LIMITATIONS OF THE PROCEDURE

• FOR RESEARCH USE ONLY. NOT FOR USE IN DIAGNOSTIC PROCEDURES.
• The kit should not be used beyond the expiration date on the kit label.
• Do not mix or substitute reagents with those from other lots or sources.
• Any variation in pipetting and washing techniques, incubation time or temperature, or kit age can cause variation in the density of spots, intensity of specific staining, and background levels.

TECHNICAL HINTS

• To minimize edge effect, place the microplate (bottom down) onto a piece of aluminum foil (about 4 x 6 inches). Add cells, cover the microplate with the lid, and shape the foil around the edges of the microplate. The foil may be left on the microplate for the rest of the experimental procedure and removed after the BCIP/NBT has been washed off.
• Do not remove the flexible plastic underdrain on the bottom of the microplate before or during incubation and development. It may damage the PVDF membrane filter. The underdrain cover may be removed only after completing the incubation with BCIP/NBT Substrate.
• Do not touch PVDF membrane filters with pipette tips when pipetting cells and reagents to avoid damage to the membrane.
• Upon completing the experiment, do not dry the microplate at a temperature above 37 °C. It may cause the PVDF membrane filters to crack.
• The 96-well microplate provided in this kit is not sterile. Due to the short incubation period and the presence of antibiotics in the culture media, microbial contamination has not been shown to be an issue with this ELISpot procedure.
• This kit is designed for single use only. The layout of the assay should be carefully planned to maximize the use of the provided microplate and reagents.
• The controls listed are recommended for each ELISpot experiment:
  Positive Control - Use recombinant mouse IL-2.
  Unstimulated/Negative Control - Use the same number of unstimulated cells as stimulated cells.
  Background Control - Use sterile culture media.
  Detection Antibody Control - Substitute phosphate buffered saline for detection antibody.
Incubate IL-2-secreting cells in an antibody-coated well.

Remove cells by washing. Secreted IL-2 is captured by the immobilized antibody.

Incubate with biotinylated anti-IL-2 antibody.

Incubate with alkaline phosphatase conjugated streptavidin.

Add BCIP/NBT Substrate

Add substrate and monitor the formation of colored spots.
MATERIALS PROVIDED & STORAGE CONDITIONS

Store the unopened kit at 2-8 °C. Do not use past kit expiration date.

Note: This kit is validated for single use only. Results obtained using previously opened or reconstituted reagents may not be reliable.

OTHER SUPPLIES REQUIRED

- Pipettes and pipette tips
- Deionized water
- Squirt bottle, manifold dispenser, or automated microplate washer
- 500 mL graduated cylinder
- 37 °C CO₂ incubator
- Sterile culture media
- Dissection microscope or an ELISpot reader
**PRECAUTIONS**

BCIP/NBT is toxic if swallowed, in contact with skin, or if inhaled. It is a highly flammable liquid and vapor may cause serious irritation and damage to organs. Do not eat, drink, or smoke when using this product. Do not breathe fumes. Use only in a well-ventilated area. Keep away from heat, sparks, open flames, and hot surfaces. Keep the container tightly closed.

Some components of this kit contain sodium azide, which may react with lead and copper plumbing to form explosive metallic azides. Flush with large volumes of water during disposal.

Some components in this kit contain a preservative which may cause an allergic skin reaction. Avoid breathing mist.

Wear protective gloves, clothing, eye, and face protection. Wash hands thoroughly after handling. Refer to the MSDS on our website prior to use.

**REAGENT PREPARATION**

Bring all reagents to room temperature, except the Detection Antibody Concentrate and Dilution Buffer 1, which should remain at 2-8 °C.

**Wash Buffer** - If crystals have formed in the concentrate, warm to room temperature and mix gently until the crystals have completely dissolved. To prepare Wash Buffer, add 50 mL of Wash Buffer Concentrate to 450 mL of deionized water and mix well.

**Mouse IL-2 Positive Control** - Reconstitute the lyophilized Mouse IL-2 Control with 250 μL of culture medium that is used to incubate cells.

**Detection Antibody** - Tap or vortex the vial to release reagent collected in the cap. Transfer 100 μL of Detection Antibody Concentrate into the vial labeled Dilution Buffer 1 and mix well. For optimal performance, prepare the detection antibody mixture immediately before use.

**Streptavidin-AP Concentrate A** - Tap or vortex the vial to release reagent collected in the cap. Transfer 100 μL of Streptavidin-AP Concentrate A into the vial labeled Dilution Buffer 2 and mix well. For optimal performance, prepare the Streptavidin-AP immediately before use.

**SAMPLE PREPARATION**

The types of effector and responder cells used, method of cell separation, mode of stimulation, and length of incubation are to be determined by each investigator.
ASSAY PROCEDURE

Bring all reagents to room temperature, except the diluted Detection Antibody mixture, which should remain at 2-8 °C. All samples and controls should be assayed at least in duplicate.

1. Fill all wells in the microplate with 200 μL of sterile culture media and incubate for approximately 20 minutes at room temperature.

2. When cells are ready to be plated, aspirate the culture media from the wells. Immediately add 100 μL of the appropriate cells or controls to each well (see Technical Hints for appropriate controls).

3. Incubate cells in a humidified 37 °C CO₂ incubator. Optimal incubation time for each stimulus should be determined by the investigator. **Do not disturb the cells during the incubation period.**

4. Aspirate each well and wash, repeating the process three times for a total of four washes. Wash by filling each well with Wash Buffer (250-300 μL) using a squirt bottle, manifold dispenser, or autowasher. Complete removal of liquid at each step is essential to good performance. After the last wash, remove any remaining Wash Buffer by aspirating or decanting. Invert the plate and blot it against clean paper towels. **Note:** Adjust the height of the prongs of the manifold dispenser or autowasher to prevent damage to the membranes.

5. Add 100 μL of Detection Antibody mixture into each well, and incubate overnight at 2-8 °C. Alternatively, incubation with detection antibodies can be done for 2 hours at room temperature on a rocking platform.

6. Repeat the wash procedure described in step 4.

7. Add 100 μL of diluted Streptavidin-AP Concentrate A into each well, and incubate for 2 hours at room temperature.

8. Repeat the wash procedure described in step 4.

9. Add 100 μL of BCIP/NBT Substrate into each well, and incubate for 1 hour at room temperature. **Protect from light.**

10. Decant the BCIP/NBT Substrate from the microplate and rinse the microplate with deionized water. Invert the microplate and tap to remove excess water. Remove the flexible plastic underdrain from the bottom of the microplate, wipe the bottom of the plate thoroughly with paper towels and dry completely either at room temperature (60-90 minutes) or 37 °C (15-30 minutes).
CALCULATION OF RESULTS

The developed microplate can be analyzed by counting spots using either a dissection microscope or an ELISpot reader. Specific spots are round and have a dark center with slightly fuzzy edges. Quantitation of results can be done, for example, by calculating the number of spot forming cells (SFC) per number of cells added to the well.

REPRODUCIBILITY DATA

Splenocytes from a C57BL mouse (1 x 10^5 cells/mL) were stimulated with 50 ng/mL of phorbol 12-myristate-13-acetate (PMA) and 0.5 µg/mL of calcium ionomycin overnight at 37 °C in a 5% CO₂ incubator. The sample was assayed in seven wells according to the procedure and analyzed with a dissection microscope.
